ABSTRACT:

A wireless communication product fulfillment system is disclosed. This system includes a computerized management technique for maintaining inventory data, ordering data, assembly data, and shipping data regarding wireless communication product kits of different configurations. These kits may correspond to orders from agents of different wireless communication service providers. The kit configurations may each specify a different brand of wireless communication device, such as a wireless telephone or pager. The fulfillment system further facilitates efficient operation by direct electronic data interfacing with multiple ordering agents and wireless communication service carriers.

ABSTRACT:

A system for extended enterprise planning across a supply chain is provided. The system includes transactional execution system layers (14, 18) for a demand enterprise (10) and a supply enterprise (12). First and second federated electronic planning interchange layers (16, 20) provide a data specification format and an external communication interface for transactional execution system layers (14, 18). A supply chain planning engine (22), operable to perform planning for the supply chain, is in communication with a third federated electronic planning interchange layer (24) which provides a data specification format and an external communication interface for the supply chain planning engine (22). A data access/transfer layer (28) interconnects and allows transfer of information between the first, second and third electronic federated planning interchange layers (16, 20, 24). The supply chain planning engine (22), the first transactional execution system (14) and the second transactional execution system (18) can thereby communicate data which the supply chain planning engine (22) can use to provide constraint based extended enterprise planning across the supply chain.

ABSTRACT:

This invention relates to a production system for retail goods which is intended for timely collection of accurate sales information from retail outlets and flexible production of goods in accordance with the same information, and comprises a retail sales information collecting means, a production quantity setting means for determining a production quantity according to the information so collected, a directing means for directing the preparation and production of raw materials according to the determined production quantity, and a production means for producing the determined production quantity according to a direction to produce. Also provided is a raw materials ordering system, which determines production quantities of raw materials in accordance with production plans for ensuring flexible production of the products without the disadvantage of carrying excessive inventories and for economical and efficient control and supply of raw materials. As such, the system comprises an order quantity determining means for setting or modifying daily required quantities of raw materials in response to setting or modification of daily production plans and determining order quantities according to raw material attributes, inventories, order backlogs, in-process order quantities and the required quantities of raw materials and a data input processing means for modifying the raw material inventory quantities upon receipt of raw material acceptance information. Furthermore, another type of the raw material ordering system disclosed in this application can be employed for those raw materials that require processing after placement of an order.

ABSTRACT:

To obtain a production planning system permitting an allowance of the accuracy of production designation information between preceding and following production plans in order to follow the fluctuation of product demand forecast and received orders, a time frame comprising a series of time buckets from T1 to Tn in which the production quantity and the fluctuation width of type of product become more rough for further portion of a production plan are generated and a product quantity and type of product at a certain planned point of time are allocated to each of the time buckets from T1 to Tn. As a production period comes nearer, the time buckets are finely divided and recombined to successively decide planned production quantity and type of product. In this case, an executable production designation is automatically generated by referring to a condition storing module 3 which stores the conditions for dividing and recombining the quantity and type of product.

Document Number 3

Entry 3 of 3

File: USPT

Aug 12, 1997

DOCUMENT-IDENTIFIER: US 5657453 A

TITLE: Successively-deciding production planning system

BSPR:

Problem 1: Further production plan is extremely minute and the number of data values is too many. That is, as shown in FIG. 14, the production preparation using the further production plan includes a line working plan (capacity plan) and part ordering, which frequently uses macro information such as monthly total and total of type-of-product groups compared with the very near plan. For example, the production preparations <1> and <2> in FIG. 14 are performed by using the total value in June. This is because the accuracy of macro information is higher than that of detailed information though detailed production plan information is frequently modified later even if it is used. However, all existing production plans require a large amount of data because they are expressed with micro information.

ABSTRACT:

A system and method for evaluating an inventory management strategy combines multiple management strategies in a single inventory management system. The system analyzes the inventory portfolio on an item-by-item basis to assign the most suitable management strategy for that item. The inventory management system provides a high level of flexibility for the users to define input parameters to ensure a desired level of customer satisfaction. Additionally, it determines whether the inventory items are forecastable before predicting future demands.

ABSTRACT:

The present invention relates to an inventory control system (10) comprising: a portable computer (12) having a portable computer stylus (12E) which has at least one portable computer stylus button (12EB). A portable printer (14) is electrically connected to the portable computer CPU (12A). A computer software (16) is contained within the portable computer (12). The computer software (16) comprises computer software inventory (16A) having computer software inventory items. The

computer software (16) further comprises a separate computer software check box (16B) corresponding to each computer software inventory item. The computer software check box (16B) is positioned adjacent to and correlating with each computer software inventory item. The computer software (16) further comprises a separate computer software quantity (16C) corresponding to each computer software inventory item. The computer software quantity (16C) is positioned adjacent to and correlating with each computer software inventory item. The computer software (16) further comprises a separate computer software damage (16D) corresponding to each computer software inventory item. The computer software (16) further comprises a computer software disclaimer (16E) which comprises a computer software pick up disclaimer (16EA) having a computer software pick up disclaimer signature line (16EAA) and a computer software pick up disclaimer computer generated date (16EAB). The computer software disclaimer (16E) further comprises a computer software deliver disclaimer (16EB) having a computer software deliver disclaimer signature line (16EBA) and a computer software deliver disclaimer computer generated date (16EBB). The computer software (16) further comprises a computer software control (16F) which comprises computer software ON/OFF control (16FG) and a computer software print control (16FH).

ABSTRACT:

In accordance with the present invention, a requisition and inventory management system is provided which employs both a host computer and a local computer which can be linked to permit two-way data communications in a real time environment. Each computer has an associated database which can be accessed by that computer. By accessing its respective database, each computer can build and transmit to the other computer communications blocks of data relating to a particular requisition of an item in Just-in-Time (JIT) inventory or to the management of the JIT inventory. The other computer can then use the received data to continue processing of the requisition or to update its JIT inventory records. Thus requisition records are created from a real-time interaction between the host and local computers, with each computer using data from its respective database in conjunction with information entered by a Customer Service Representative (CSR) operating the local computer.

The system of the present invention also utilizes means for automatically determining which items in the JIT inventory are likely to require replenishment. The system then proposes a purchase or transfer order for an optimum quantity of the item, which the CSR may accept or modify.

ABSTRACT:

This invention relates to a production system for retail goods which is intended for timely collection of accurate sales information from retail outlets and flexible production of goods in accordance with the same information, and comprises a retail sales information collecting means, a production quantity setting means for determining a production quantity according to the information so collected, a directing means for directing the preparation and production of raw materials according to the determined production quantity, and a production means for producing the determined production quantity according to a direction to produce. Also provided is a raw materials ordering system, which determines production quantities of raw materials in accordance with production plans for ensuring flexible production of the products without the disadvantage of carrying excessive inventories and for economical and efficient control and supply of raw materials. As such, the system comprises an order quantity determining means for setting or modifying daily required quantities of raw materials in response to setting or modification of daily production plans and determining order quantities according to raw material attributes, inventories, order backlogs, in-process order quantities and the required quantities of raw materials and a data input processing means for modifying the raw material inventory quantities upon receipt of raw material acceptance information. Furthermore, another type of the raw material ordering system disclosed in this application can be employed for those raw materials that require processing after placement of an order.

ABSTRACT:

This invention relates to a production system for retail goods which is intended for timely collection of accurate sales information from retail outlets and flexible production of goods in accordance with the same information, and comprises a retail sales information collecting means, a production quantity setting means for determining a production quantity according to the information so collected, a directing means for directing the preparation and production of raw materials according to the determined production quantity, and a production means for producing the determined production quantity according to a direction to produce. Also provided is a raw materials ordering system, which determines production quantities of raw materials in accordance with production plans for ensuring flexible production of the products without the disadvantage of carrying excessive inventories and for economical and efficient control and supply of raw materials. As such, the system comprises an order quantity determining means for setting or modifying daily required quantities of raw materials in response to setting or modification of daily production plans and determining order quantities according to raw material attributes, inventories, order backlogs, in-process order quantities and the required quantities of raw materials and a data input processing means for modifying the raw material inventory quantities upon receipt of raw material acceptance information. Furthermore, another type of the raw material ordering system disclosed in this application can be employed for those raw materials that require processing after placement of an order.

ABSTRACT:

A fast computer implemented method generates near-optimal solutions to the multi-objective inventory matching problem by solving for multiple objectives simultaneously and generating multiple non-dominating solutions. The method implements a multi-assignment backjumping algorithm that consists of three steps. The first step is a rappelling step in which a feasible solution is created by applying Iterative Bipartite Matching and maximum flow algorithm. Near-optimal feasible solutions are stored in a non dominated set. The second step is to use a multi-key sort to identify undesirable matches in a given feasible solution. The third step is backlifting the solution by removing undesirable matches from the feasible solution and places those undesirable matches on a no good set of matches. If the feasible solution is non-dominated, a copy is stored in a non-dominated set. The feasible solution is finally provided as input to the repelling step.

DOCUMENT-IDENTIFIER: US 6044361 A

TITLE: Fast inventory matching algorithm for the process industry

BSPR:

A search for a solution to the inventory problem is done in the space of matches (i.e., arcs of the bipartite graph) by creating a solution by instantiating one match at a time. In this context, instantiating a match would imply choosing a MU.sub.size and a MU.sub.number for the associated match. This search can be either a depth-first, breadth-first or a best-first (especially, if we have a good evaluation function for partial solutions). Therefore, the search progresses iteratively, expanding one match at a time, and then backtracking to cover all possibilities. Such an enumerative search procedure can be represented using tree structure where the intermediate nodes represent partial solutions and the leaf nodes represent complete solutions. Note that a child node is derived from a parent node expanding one match. This tree representation is called a search tree. Clearly, a naive approach to search is exponential. For example, typical problem instances with 200 orders and 100 slabs with an edges density of 5% would have 1000 edges. Assuming that we fix the MU.sub.size arbitrarily at MU.sub.min and the average number of integer values for MU.sub.number on each edge is 5, then we have a search space of 5.sup.1000 which is a very large number and a naive search would return good solutions in limited time only by chance.

PRIMARY-EXAMINER: Peeso; Thomas R.

ABSTRACT:

An excess inventory system monitors excess material. In the system, requirements are determined for each component part over a predetermined period (e.g., 6 months) from material requirements planning (MRP) data. When forecasting for the component part is to be

planning (MRP) data. When forecasting for the component part is to be determined using an MRP planning method, the MRP data is used to determine a number of excess component parts. The number of excess components is then recorded in a record for the component part within an excess inventory table. When forecasting for the component part is to be determined using an alternate planning method which is alternate to MRP, the alternate planning method is used to determine a number of excess component parts. The number of excess components and a notation indicating the alternate planning method used are then recorded in the record for the component part within the excess inventory table.

File: USPT

Sep 28, 1999

DOCUMENT-IDENTIFIER: US 5960414 A

TITLE: Method for monitoring excess inventory

BSEQ:

excess component parts=number of component parts on hand+number of component parts on order-requirements for the component part over the predetermined period.

DRPR:

FIG. 3 is a flowchart which shows process flow for a strip module in an excess inventory system in accordance with a preferred embodiment of the present invention.

DEPR:

Copy management module 27 allows records within excess inventory detail table 25 to be carried over from month to month. Copy management module 28 performs a summary roll-up from excess inventory detail table 25 to financially summarized excess inventory data table 29. Additionally Load program 30 is used to add or update information in financially summarized excess inventory data table 29. Financially summarized excess inventory data table 29 can be updated less frequency, for example, at the end of each month.

DEPR:

All information in excess inventory detail table 25 and financially summarized excess inventory data table 29 is organized in a hierarchical structure with the larger information categories (i.e. current month, plant, MRP controller, material number) supported by smaller tactical data (i.e. excess quantity, open order quantity). User generated reports are provided through a graphical interface which allows individuals to see which smaller data pieces are supporting the higher level data.

CLEQ:

excess component parts=number of component parts on hand +number of component parts on order-requirements for the component part over the predetermined period.

CLEQ:

excess component parts=number of component parts on hand +number of component parts on order-requirements for the component part over the predetermined period.
